

MULTIQUASIGROUPS AND SOME RELATED STRUCTURES

Прилози, мат.-техн. науки, МАНУ, Скопје, I 2 (1980), 5–12

G. ČUPONA, J. UŠAN, Z. STOJAKOVIĆ

The purpose of this paper is to show that the class of multi-quasigroups is a convenient extension of the class of quasigroups. In the first part of the paper we give four interpretations of the notion of an $[n, m]$ -quasigroup: (i) as a structure with a „vector valued“ operation, (ii) as an algebra with a strongly orthogonal system of quasigroups, (iii) as an algebra with an orthogonal system of operations, and (iv) as a structure with a finitary relation. In the second part of the paper we show that on each (nontrivial) $[n, m]$ -quasigroup it can be constructed an n -dimensional $n + m$ -net, and conversely, each n -dimensional $n + m$ -net can be coordinatized by an $[n, m]$ -quasigroup. Partial multi-quasigroups are considered in the third part of the paper, and it is shown that every partial $[n, m]$ -quasigroup can be embedded in an $[n, m]$ -quasigroup.

1. Let Q be a nonempty set, n and m positive integers, and $f: (x_1, \dots, x_n) \mapsto f(x_1, \dots, x_n)$ a mapping from Q^n into Q^m . Then we say that $Q(f)$ is an $[n, m]$ -groupoid, and the n -ary operations f_1, f_2, \dots, f_m defined by:

$$f(x_1, \dots, x_n) = (y_1, \dots, y_m) \Leftrightarrow (\forall i \in N_m) y_i = f_i(x_1, \dots, x_n),$$

are called the component operations of f and this is denoted by $f = (f_1, \dots, f_m)$.

An $[n, m]$ -groupoid $Q(f)$ is said to be an $[n, m]$ -quasigroup iff the following statement is satisfied:

(A). For each „vector“ $(a_1, \dots, a_n) \in Q^n$ and each injection φ from $N_n = \{1, 2, \dots, n\}$ into N_{n+m} , there exists a unique vector $(b_1, \dots, b_{n+m}) \in Q^{n+m}$ such that $b_{\varphi(i)} = a_i, \dots, b_{\varphi(n)} = a_n$ and:

$$f(b_1, \dots, b_n) = (b_{n+1}, \dots, b_{n+m}). \quad (1)$$

It is clear that the following proposition is satisfied.

1.1. An $[n, m]$ -groupoid $Q(f)$ is an $[n, m]$ -quasigroup iff the sequence f_1, \dots, f_m of component operations of f satisfies the statement (A') which is obtained from (A) by replacing (1) by: $(\forall i \in N_m) f_i(b_1, \dots, b_n) = b_{n+i}$. \square

A sequence f_1, \dots, f_m of n -ary operations on a set Q is said to be a strongly orthogonal system of operations if it satisfies the statement (A'). And, a sequence g_1, \dots, g_{n+m} of n -ary operations on a set Q is called orthogonal if the following statement is satisfied.

(B). For each $(a_1, \dots, a_n) \in Q^n$ and each injection $\varphi: N_n \rightarrow N_{n+m}$ there exists a unique vector $(c_1, \dots, c_n) \in Q^n$ such that:

$$(\forall i \in N_n) g_{\varphi(i)}(c_1, \dots, c_n) = a_i.$$

The following proposition shows that there is an equivalence between the notions of orthogonal system of operations and $[n, m]$ -quasigroups.

1.2. An $[n, m]$ -groupoid $Q(f)$ is an $[n, m]$ -quasigroup iff there exists an orthogonal system of n -ary operations g_1, \dots, g_{n+m} such that:

$$f(x_1, \dots, x_n) = (x_{n+1}, \dots, x_{n+m}) \Leftrightarrow (\exists t_1, \dots, t_n \in Q) (\forall i \in N_{n+m}) x_i = g_i(t_1, \dots, t_n). \quad (2)$$

Proof. If $Q(f)$ is an $[n, m]$ -quasigroup and if g_1, \dots, g_{n+m} are defined by $f(x_1, \dots, x_n) = (x_{n+1}, \dots, x_{n+m}) \Leftrightarrow (\forall i \in N_{n+m}) x_i = g_i(x_1, \dots, x_n)$, then an orthogonal system of n -ary operations g_1, \dots, g_{n+m} is obtained.

And conversely, if g_1, \dots, g_{n+m} is an orthogonal system of n -ary operations on Q , and if the $[n, m]$ -groupoid $Q(f)$ is defined by (2), then $Q(f)$ is an $[n, m]$ -quasigroup. \square

As a consequence from 1.1 and 1.2 (or directly) we obtain the following connection between orthogonal and strongly orthogonal systems of operations.

1.3. A sequence of n -ary operations f_1, \dots, f_m on a set Q is a strongly orthogonal system iff the sequence $g_1, \dots, g_n, f_1, \dots, f_m$ is an orthogonal system, where g_1, \dots, g_n are defined by: $(\forall i \in N_n) g_i(x_1, \dots, x_n) = x_i$. \square

It is easy to see that in a strongly orthogonal system of n -ary operations on a set Q all operations are n -quasigroups.

An orthogonal system of n -quasigroups for $n = 2$ is a strongly orthogonal system, but for $n > 2$ a system of n -quasigroups which is an orthogonal system need not be a strongly orthogonal system.

An $n + m$ -ary relation $\rho \in Q^{n+m}$ is called an $[n, m]$ -quasigroup relation if it satisfies the statement (A'') obtained from (A) by replacing (1) by: $\rho(b_1, \dots, b_{n+m})$.

The proof of the following proposition is also clear.

1.4. $Q(f)$ is an $[n, m]$ -quasigroup iff the relation ρ defined by:

$$\rho(x_1, \dots, x_{n+m}) \Leftrightarrow f(x_1, \dots, x_n) = (x_{n+1}, \dots, x_{n+m})$$

is an $[n, m]$ -quasigroup relation. \square

Thus, we obtained four interpretations of the notion of $[n, m]$ -quasigroup. Further on we shall use mainly the last interpretation, i.e. by an " $[n, m]$ -quasigroup" we shall mean a structure $Q(\rho)$ where ρ is an $[n, m]$ -quasigroup relation. Then, we shall sometimes say that $Q(\rho)$ is a „multi-quasigroup“, if it is not necessary to emphasize n and m .

The proofs of the following properties are straightforward.

1.5. Let $\rho \subseteq Q^{n+m}$ and ψ be a permutation of N_{n+m} . Then $Q(\rho)$ is an $[n, m]$ -quasigroup iff $Q(\rho_\psi)$ is an $[n, m]$ -quasigroup, where:

$$\rho_\psi(x_1, \dots, x_{n+m}) \Leftrightarrow \rho(x_{\psi(1)}, \dots, x_{\psi(n+m)}). \quad \square$$

$Q(\rho_\psi)$ is called ψ parastrophe of the multiquasigroup $Q(\rho)$.

1.6. Let $\rho \subseteq Q^{n+m}$ and let $\xi = (\xi_1, \dots, \xi_{n+m})$ be a sequence of permutations of Q . Then $Q(\rho)$ is an $[n, m]$ -quasigroup iff $Q(\rho^\xi)$ is an $[n, m]$ -quasigroup, where:

$$\rho^\xi(x_1, \dots, x_{n+m}) \Leftrightarrow \rho(\xi_1(x_1), \dots, \xi_{n+m}(x_{n+m})). \quad \square$$

$Q(\rho^\xi)$ is called ξ -isotope of $Q(\rho)$.

1.7. Let $Q(\rho)$ be an $[n, m]$ -quasigroup, $a_1, \dots, a_k \in Q$, $k < n$, and φ an injection from Q^k into Q^n . Then $Q(\rho')$ is also an $[n-k, m]$ -quasigroup, where:

$$\rho'(x_1, \dots, x_{n+m-k}) \Leftrightarrow \rho(x_1, \dots, x_{n+m}) \wedge (\forall i \in N_k) x_{\varphi(i)} = a_i. \quad \square$$

1.8. An $[n, 1]$ -groupoid $Q(f)$ is an $[n, 1]$ -quasigroup iff $Q(f)$ is an n -quasigroup. \square

1.9. $Q(\rho)$ is a $[1, m]$ -quasigroup iff there is a sequence ξ_1, \dots, ξ_m of permutations of Q such that:

$$\rho(x, x_1, \dots, x_m) \Leftrightarrow (\forall i \in N_m) x_i = \xi_i(x). \quad \square$$

1.10. If $|Q| = 1$, and $\rho = Q^{n+m}$, then $Q(\rho)$ is an $[n, m]$ -quasigroup.

An $[n, m]$ -quasigroup $Q(\rho)$ is called nontrivial if $|Q| \geq 2$, $n \geq 2$, $m \geq 1$.

We remark that:

(i) The assumption that m and n are positive integers may be omitted, and then we would obtain that there exist only trivial $[0, m]$ -quasigroups, and $[n, 0]$ -quasigroups. Namely, $Q(\rho)$ is an $[n, 0]$ -quasigroup iff $\rho = Q^n$, and $Q(\rho)$ is a $[0, m]$ -quasigroup iff $|\rho| = 1$.

(ii) The notion of an $[n, m]$ -loop can be defined in a usual way, but it is easy to see that proper multiloops do not exist. We do not see any convenient definition of a proper multigroup.

2. Let \mathbf{P} and \mathbf{B} be two nonempty sets, $\mathbf{B} = \mathbf{B}_1 \cup \dots \cup \mathbf{B}_{n+m}$ a partition of \mathbf{B} , where $n \geq 2$, $m \geq 1$, and I is a subset of $\mathbf{P} \times \mathbf{B}$ (the elements of \mathbf{P} are called „points“ and those of \mathbf{B} „blocks“.) The structure $(\mathbf{P}; \mathbf{B}_1, \dots, \mathbf{B}_{n+m}; I)$ is called an n -dimensional $n + m$ -net (or simply: an $[n, n + m]$ -net) if the following statements are satisfied.

(i) If $p \in \mathbf{P}$ then there exists exactly one sequence $B_1, \dots, B_{n+m} \in \mathbf{B}$ such that $pIB_s, B_s \in \mathbf{B}_s$, for all $s \in N_{n+m}$.

(ii) If $\varphi: N_n \rightarrow N_{n+m}$ is an injection and $B_s \in \mathbf{B}_{\varphi(s)}$ then there exists exactly one $p \in \mathbf{P}$ such that pIB_s for all $s \in N_n$.

We shall show that there exists an equivalence between the theory of $[n, n + m]$ -nets and $[n, m]$ -quasigroups.

2.1. Every nontrivial $[n, m]$ -quasigroup induces an $[n, n + m]$ -net.

Proof. Let $Q(\rho)$ be a nontrivial $[n, m]$ -quasigroup. Define a set of „points“ by:

$$\mathbf{P} = \{(x_1, \dots, x_{n+m}) \mid \rho(x_1, \dots, x_{n+m})\}.$$

If $x \in Q$ and $s \in N_{n+m}$, then: $B_s^x = \{(x_1, \dots, x_{n+m}) \in \mathbf{P} \mid x_s = x\}$ is called a „block“. And, $\mathbf{B} = \{B_s^x \mid s \in N_{n+m}, x \in Q\}$ is the set of all blocks. Further, let $\mathbf{B}_1, \dots, \mathbf{B}_{n+m}$ be defined by: $\mathbf{B}_s = \{B_s^x \mid x \in Q\}$.

Clearly, \mathbf{B} is a disjoint union of $\mathbf{B}_1, \dots, \mathbf{B}_{n+m}$.

It is easy to see that $(\mathbf{P}; \mathbf{B}_1, \dots, \mathbf{B}_{n+m}; I)$ is an $[n, n + m]$ -net, where $pIB_s^x \Leftrightarrow p \in B_s^x$. (We say that this net is induced by the given multi-quasigroup.) \square

2.2. Every $[n, n + m]$ -net induces an $[n, m]$ -quasigroup.

Proof. Let $(\mathbf{P}; \mathbf{B}_1, \dots, \mathbf{B}_{n+m}; I)$ be an $[n, n + m]$ -net.

We shall show that all the sets $\mathbf{B}_1, \dots, \mathbf{B}_{n+m}$ have the same cardinal number.

First we note that (i) and $P \neq \emptyset$ imply that all the classes of blocks $\mathbf{B}_1, \dots, \mathbf{B}_{n+m}$ are nonempty.

Let $r, s \in N_{n+m}$, $r, s \notin \{i_2, \dots, i_n\}$, $1 \leq i_2 < \dots < i_n < n + m$, and choose $B_v \in \mathbf{B}_{i_v}$ in an arbitrary way. If $B \in \mathbf{B}_r$, then by (ii) there exists exactly one point p such that pIB and pIB_v for each $v \in \{2, \dots, n\}$. By (i) there exists exactly one $B' \in \mathbf{B}_s$ such that pIB' . This implies that a mapping $\psi_{sr}: B \mapsto B'$ of \mathbf{B}_r into \mathbf{B}_s is defined. In the same manner we define a mapping $\psi_{rs}: \mathbf{B}_s \rightarrow \mathbf{B}_r$. It is easy to see that $\psi_{rs}\psi_{sr} = 1_{B_r}$, $\psi_{sr}\psi_{rs} = 1_{B_s}$, and this implies that $\psi_{rs} = (\psi_{sr})^{-1}$ is a bijection.

Let Q be a set and $\varphi_i: Q \rightarrow \mathbf{B}_i$ a bijection for every $i \in N_{n+m}$. We define an $n + m$ -ary relation ρ in Q by:

$$\rho(x_1, \dots, x_{n+m}) \Leftrightarrow (\exists p \in \mathbf{P}) (\forall i \in N_{n+m}) p I \varphi_i(x_i).$$

It can be easily seen that $Q(\rho)$ is an $[n, m]$ -quasigroup, and that the $[n, n + m]$ -net induced by $Q(\rho)$ is isomorphic to the given $[n, n + m]$ -net. \square

2.3. If $Q(\rho)$ and $Q'(\rho')$ are two $[n, m]$ -quasigroups induced by an

$[n, n+m]$ -net, then they are isotopic.

Proof. Assume that $(P; B_1, \dots, B_{n+m}; I)$ is an $[n, n+m]$ -net, $\varphi_i: Q \rightarrow B_i$, $\varphi'_i: Q' \rightarrow B_i$ are bijections for each $i \in N_{n+m}$, and $Q(\rho)$, $Q'(\rho')$ are the $[n, m]$ -quasigroups defined as in the proof of 2.2.

If the sequence of bijections $\psi_1: Q \rightarrow Q', \dots, \psi_{n+m}: Q \rightarrow Q'$ is defined by $\psi_i = \varphi'_i{}^{-1} \varphi_i$ then we obtain an isotopy from $Q(\rho)$ into $Q'(\rho')$. \square

3. A substructure of an $[n, m]$ -quasigroup (in general) is not an $[n, m]$ -quasigroup, but it is a partial $[n, m]$ -quasigroup according to the following definition.

If $\rho \subseteq Q^{n+m}$ is an $n+m$ -ary relation on a nonempty set Q , then the structure $Q(\rho)$ is called a partial $[n, m]$ -quasigroup if the following condition is satisfied.

- (C) Let $\varphi: N_n \rightarrow N_{n+m}$ be an injection. If $\rho(x_1, \dots, x_{n+m}), \rho(y_1, \dots, y_{n+m})$ and $(\forall i \in N_n) x_{\varphi(i)} = y_{\varphi(i)}$ then $(\forall j \in N_{n+m}) x_j = y_j$.

Clearly:

3.1. Every $[n, m]$ -quasigroup is a partial $[n, m]$ -quasigroup, and the class of partial $[n, m]$ -quasigroups is hereditary.

Now, we shall show that:

3.2. Every partial $[n, m]$ -quasigroup $R(\rho)$ is a substructure of an $[n, m]$ -quasigroup $R'(\rho')$.

Proof. Let $\varphi: N_n \rightarrow N_{n+m}$ be an injection, and D_R^φ the subset of R^n defined by:

$(a_1, \dots, a_n) \in D_R^\varphi \Leftrightarrow (\exists b_1, \dots, b_{n+m}) [\rho(b_1 \dots b_{n+m}) \wedge (\forall i \in N_n) a_i = b_{\varphi(i)}]$. Denote R by R_φ , and ρ by ρ_φ . Assume that $R_k(\rho_k)$ is a partial $[n, m]$ -quasigroup, and define $R_{k+1}(\rho_{k+1})$ in the following way.

Let $\mathbf{a} = (a_1, \dots, a_n) \in R_k^n \setminus D_k^{\varphi^{-1}}$, where $\varphi: N_n \rightarrow N_{n+m}$ is an injection. Define a sequence $(1_{\mathbf{a}\varphi}, \dots, (n+m)_{\mathbf{a}\varphi})$ in the following way

$$(\forall i \in N_n) i_{\mathbf{a}\varphi} = a_i \text{ and } (\mathbf{a}, D_k^\varphi) = \{j_{\mathbf{a}\varphi} \mid j \notin \{\varphi(1), \dots, \varphi(n)\}\}$$

consists of m elements and it is disjoint with R_k ; it is also assumed that:

$$(\mathbf{a}, D_k^\varphi) \cap (\mathbf{b}, D_k^\varphi) \neq \emptyset \Leftrightarrow \mathbf{a} = \mathbf{b} \wedge \varphi = \psi.$$

Now, we define the structure $R_{k+1}(\rho_{k+1})$ by:

$$R_{k+1} = R_k \cup \bigcup_{\varphi, \mathbf{a}} (\mathbf{a}, D_k^\varphi), \quad \rho_{k+1} = \rho_k \cup \{1_{\mathbf{a}\varphi} \dots (n+m)_{\mathbf{a}\varphi} \mid \mathbf{a} \in R_k^n \setminus D_k^{\varphi^{-1}}, \varphi\}.$$

It can be easily seen that $R_{k+1}(\rho_{k+1})$ is a partial $[n, m]$ -quasigroup.

Finally, let $R'(\rho')$ be defined by: $R' = \bigcup_k R_k$, $\rho' = \bigcup_k \rho_k$.

The structure $R'(\rho')$ is a partial $[n, m]$ -quasigroup, for it is the union of the chain $\{R_k(\rho_k) \mid k=1, 2, \dots\}$ of partial $[n, m]$ -quasigroups, such that $R_k^\varphi \subseteq D_{k+1}^{\varphi^{-1}}$ for each injection $\varphi: N_n \rightarrow N_{n+m}$, and this implies that $R'(\rho')$ is an $[n, m]$ -quasigroup.

It is natural to say that $R'(\rho')$ is the universal covering of $R(\rho)$. The universal covering $B'(\rho')$ of the partial $[n, m]$ -quasigroup $B(\emptyset)$ is in fact the free $[n, m]$ -quasigroup with a base B .

As consequences of 3.2 we obtain the following propositions.

3.3. If Q is an infinite set then there exists an $[n, m]$ -quasigroup $Q(\rho)$. \square

3.4. The free $[n, m]$ -quasigroup with a finite (non-empty) base is countable and infinite. \square

¹ $D_k^\varphi = D_{R_k}^\varphi$

Making an obvious modification of the proof of 3.2, we obtain that the following statement is also satisfied.

3.5. Let $\varphi: N_n \rightarrow N_{n+m}$ be an injection, and $R(\rho)$ a partial $[n, m]$ -quasigroup such that $D_R^\varphi \neq R^n$. There exists a partial $[n, m]$ -quasigroup $Q(\rho)$ with the following properties:

- (i) $Q(\rho)$ is an extension of $R(\rho)$;
- (ii) $\psi: N_n \rightarrow N_{n+m}$ is an injection such that $D_Q^\psi = Q^n$ iff $\psi = \varphi$;
- (iii) If R is infinite then $|R| = |Q|$.

Denote by $\Sigma_R^{n, m}$ the set of $n+m$ -ary relations ρ on a set R such that $R(\rho)$ is a partial $[n, m]$ -quasigroup. By an application of Zorn's lemma we obtain the following proposition.

3.6. Every relation $\rho \in \Sigma_R^{n, m}$ is contained in a maximal relation $\tau \in \Sigma_R^{n, m}$. The following statements are also obvious.

3.7. If $\rho \in \Sigma_R^{n, m}$ and if $\varphi: N_n \rightarrow N_{n+m}$ is an injection such that $D_\rho^{\varphi^{-1}} = R^n$ then ρ is a maximal element in $\Sigma_R^{n, m}$.

3.8. If $n+m=n'+m'$ and $n \geq n'$, then $\Sigma_R^{n', m'} \subseteq \Sigma_R^{n, m}$.

Now, we shall show that every finitary relation on a set R induces a partial multiquasigroup.

3.9. If $\rho \subseteq R^k$ ($k \geq 0$), then there exist n, m such that $k = n + m$ and $R(\rho)$ is a partial $[n, m]$ -quasigroup.

Proof. If $\rho = \emptyset$ or $|\rho| = 1$, then $R(\rho)$ is a partial $[n, m]$ -quasigroup for each pair of nonnegative integers n, m such that $n+m=k$. Let $|\rho| \geq 2$, and let d be the least positive integer such that there exist two vectors \mathbf{a}, \mathbf{b} with exactly d different components (in other words, d is the "code distance" of ρ). Then, $R(\rho)$ is a partial $[k-d+1, d-1]$ -quasigroup. \square

МУЛТИКВАЗИГРУПИ И СТРУКТУРИ ПОВРЗАНИ СО НИВ

РЕЗИМЕ

Во работава се покажува дека мултиквазигрупите се подесно проширување на класата квазигрупи. Во првиот дел на работава се даваат четири интерпретации на поимот мултиквазигрупа: (i) како алгебра со една мультиоперација, (ii) како алгебра со силно ортогонален систем квазигрупи, (iii) како алгебра со еден ортогонален систем операции, и (iv) како една релативна структура. Во вториот дел се покажува дека на секоја $[n, m]$ -квазигрупа може да се конструира n -димензионална $m+n$ -решетка, а и обратно дека секоја таква решетка може да се координира со една $[n, m]$ -квазигрупа. Делумни мултиквазигрупи се разгледуваат во третиот дел, а главниот резултат на овој дел е дека секоја делумна мултиквазигрупа може да се смести во мултиквазигрупа.

¹ $(a_1, \dots, a_n) \in D_\rho^\varphi \Leftrightarrow (\exists b_1, \dots, b_{n+m}) [\rho(b_1, \dots, b_{n+m}) \wedge (\forall i \in N_n) a_i = b_{\varphi(i)}]$
